

***Using Handheld XRF
Technology to Determine
Surface Mercury
Concentration – the
Yeh/Kibogy method***

**Jannette Kibogy
API Industrial Hygiene TF Workshop
Hyatt Hotel, Denver CO
May 25th 2010**

Outline

- Mercury –Properties
- Impacts of Mercury
- Opportunity Statement
- Background on XRF
- XRF Testing and methodology
- Summary
- Questions

Unique Properties

- Only common metal liquid at room temperature
- Boiling Point: 356.73°C (674.1°F)
- Very high surface tension
- Heavy – 2 Tblsp ~ 1 lb (0.45 Kg)
- Alloys easily with other metals
- High vapor pressure – doubles every 10°C
- Vapor is colorless, tasteless, odorless
- Will “Hide” in the pores of concrete and metal

Mercury (Hg) in crude

- Naturally occurring element present in virtually all oil and gas worldwide
- Concentrations in reservoirs vary from low part per billion (ppb) to hundreds of ppb depending on geology
- Hg Species in crude appears to be largely elemental and/or inorganic compounds such as mercuric sulfide
- Hg Species from crude may accumulate in process equipment over time

Impact of Mercury in Oil Production and Processing

Mercury accumulations may require special procedures in the following areas:

■ Environment

- Potential Waste issues

■ Health: Manage Exposures from

- Volatile - Inhalation
- Absorptive - Surface contamination
- Particulate - In hot work processes

■ Safety

- Prevention of corrosion in process equipment caused by potential metal amalgamation or possible liquid metal embrittlement (LME)

Opportunity Statement

- Develop a method for proper detection of mercury surface concentrations which will assist in future planning and management of Hg containing materials
- The XRF field technique provides a significant improvement over our current best practices and is cost effective

Initial XRF testing

- Promising but missing field and lab verification data
- XRF units could easily detect the presence of high concentrations of mercury on the surface of metal > % levels
- What is needed for this method to be practical
 - A way to determine the limit of detection (LOD)
 - A way to interpret the unit readings (ppm or $\mu\text{g}/\text{cm}^2$)

Refinery Pipe Segment Analysis

- Obtained pipe from refinery
- Detected high mercury vapor readings during torch cutting (max – 3.2 mg/m³)
 - Average readings in the area >0.015 mg/m³
 - All workers wearing appropriate PPE
- The cut line had no visible mercury or vapor readings when cool, suspected mercury sulfide deposits
- Received sample sections cold cut into sample panels for XRF testing

Pipe Segment Analysis

- The prepared sample panels were tested with a vendor's demonstration XRF unit
- The results confirmed that XRF units could detect low levels of mercury surface contamination and lead us to further develop the idea of generating standard coupons for field measurement calibration
- We decided to compare two different brands of XRF machines

Pipe Segment: Hg Concentrations by Handheld XRF in $\mu\text{g}/\text{cm}^2$

- A sample grid was used to both protect the sample and guide repeatable measurements
- The field samples showed great variation in the mercury concentration deposited on the surface
- We did not know the original orientation of the pipe

Hg concentration for Section 2 varied widely and illustrates one limitation of XRF testing

➤ XRF will only see what the detection window covers

Additional analyses for Section 2, with a finer grid over the area where high concentrations were observed

Hg concentrations, in $\mu\text{g}/\text{cm}^2$

Se concentrations, in $\mu\text{g}/\text{cm}^2$

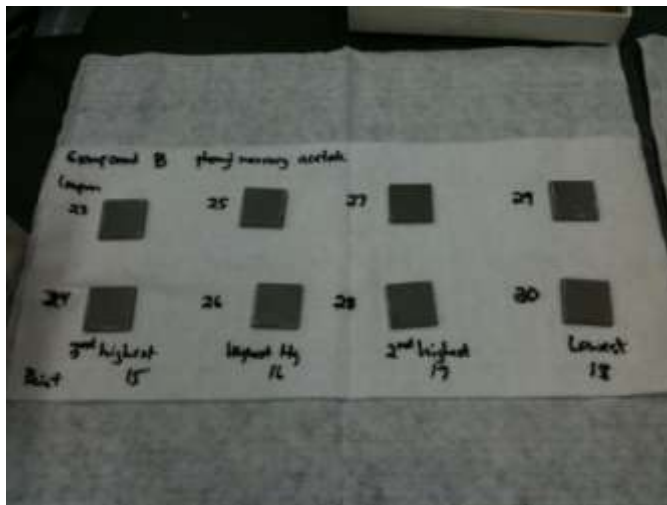

Generation of Coupon Standards for XRF testing

- XRF is limited to measuring superficial mercury
- Supported by studies of O/H pipe, subsurface pipeline and tank samples
- In these cases, the contact occurred under conditions where Hg oxide was stable
- To date we have not seen evidence that the mercury penetrates beyond the depth of XRF sensitivity
- Based on the good performance on the pipe samples a range of metal coupons were created with different surface contamination levels
- The purpose was to create standards that could be used to field calibrate a portable XRF unit and determine the Limit of Detection (LOD) on a metal substrate

Coupons were treated with Mercury containing paints

- Mimics surface contamination observed for tested specimens, in a stable, adherent matrix, clear paint was used – no pigment interference
- Range of surface concentrations 0 to 7 $\mu\text{g}/\text{cm}^2$
- Some paints formulated with inorganic Hg (HgCl_2), other with organic (diphenylmercury), and no difference in the XRF sensitivity was observed

Comparison of Instruments

Brand A Handheld XRF

- Modified the Refinery's Materials Group's instrument

Brand B Handheld XRF

- Used a demonstration instrument from a local distributor

Both instruments performed well, with R^2 for correlations between measured concentration and prepared concentrations ranging from 0.936 to 0.964

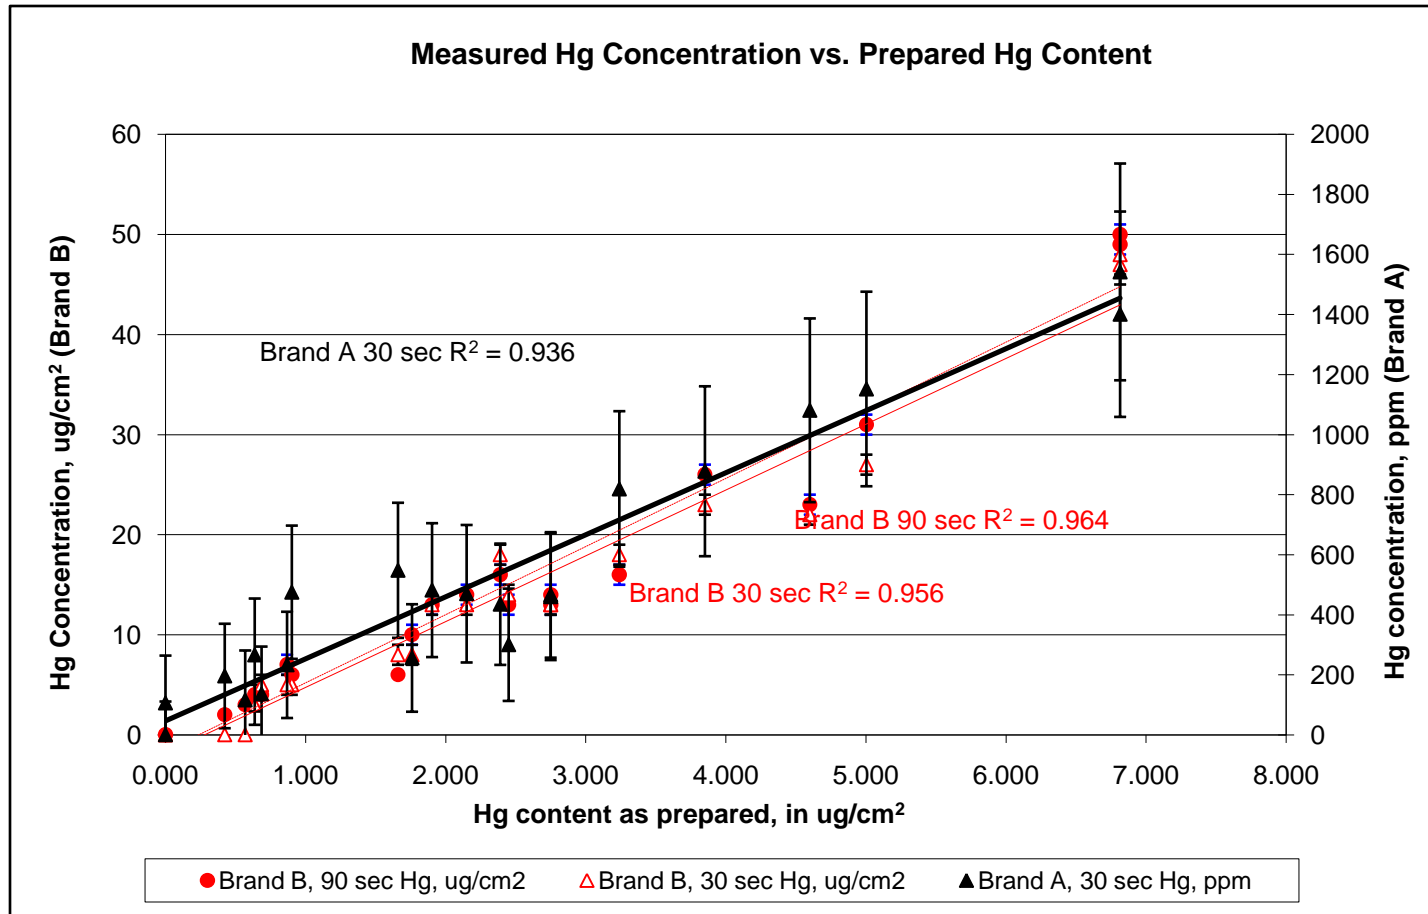

Coupons measured using both instruments at various time settings

- Each coupon was sampled by both instruments
- Data uncertainties between the two instruments are substantial
- Both units demonstrate a workable LOD with the Brand B demonstrating a lower limit

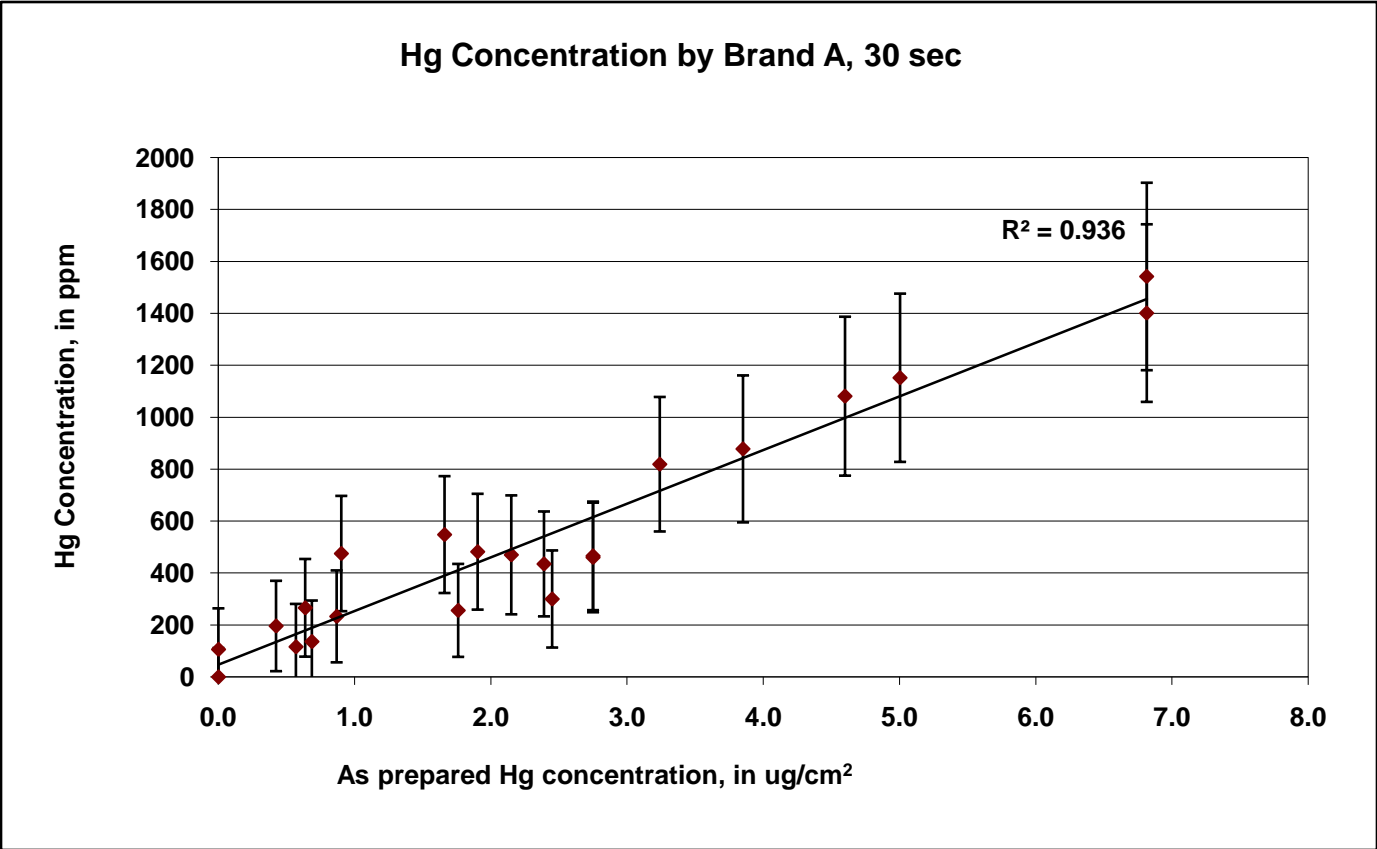

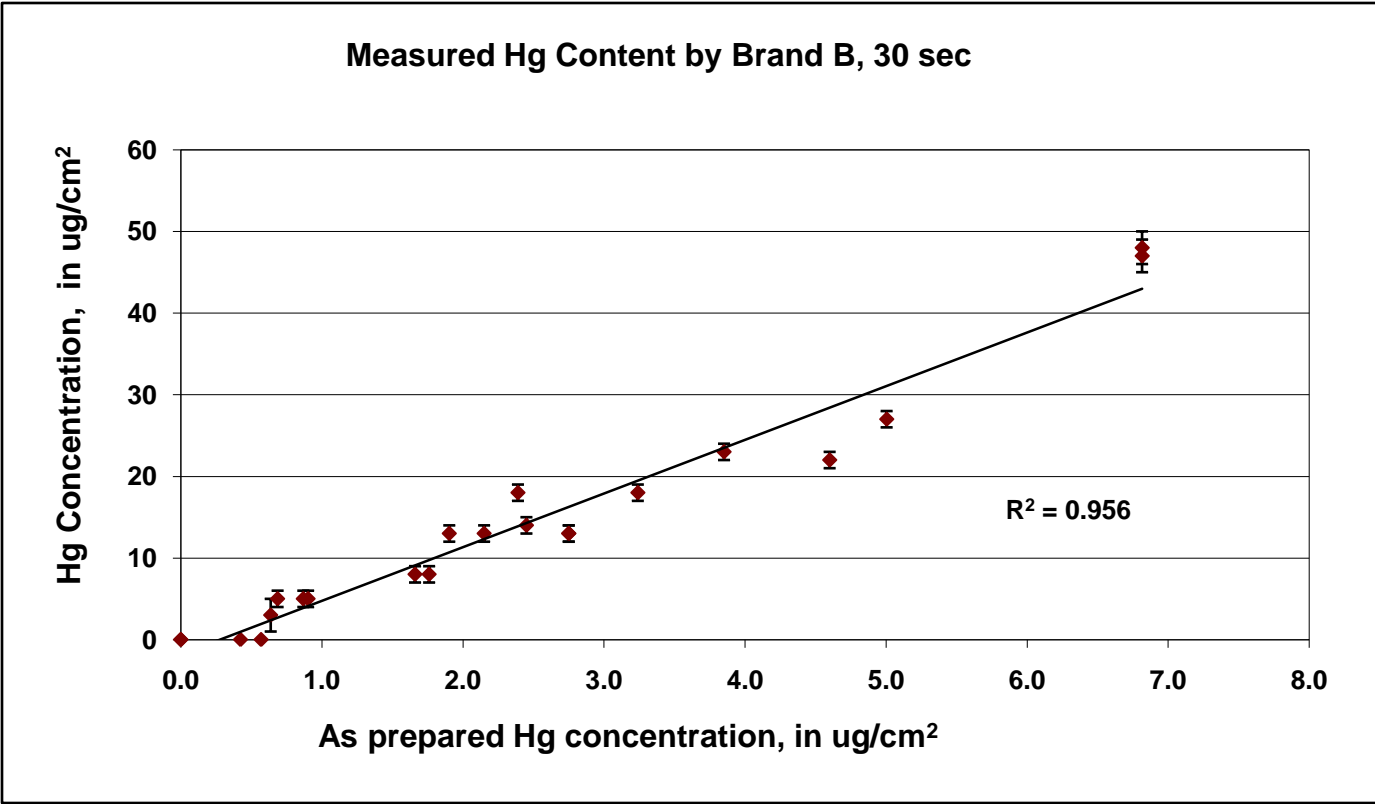

Cross-plot of measured Hg concentration vs. Hg content

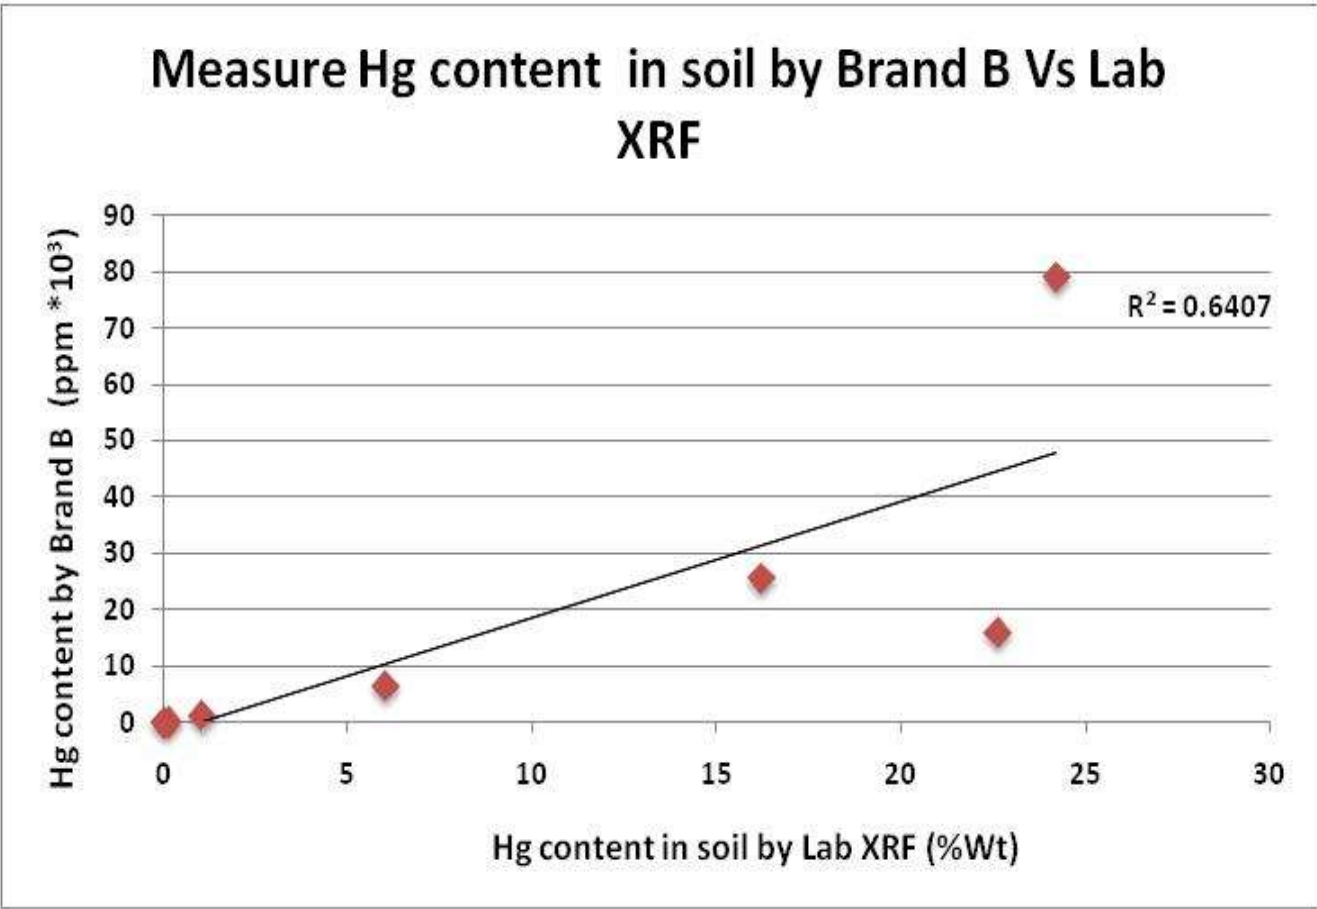

Measurement uncertainties were much larger for Brand A instrument

We favored the Brand B XRF for additional ease of use features, as well as its tighter uncertainties

Cross-plot of measured Hg concentration in soil by Brand B XRF vs. Hg content by Lab XRF

Developing a Draft “How Clean is Clean” Limit

- US EPA has issued guidance regarding the smelting of scrap cars that potentially have mercury containing electronic switches
 - The guidance uses a level of 0.5 grams mercury per 1.4 metric tons of steel – the approximate weight of a crushed car for recycling
 - Can we extrapolate/ translate this guidance into a mercury surface contamination limit in metal?
 - Will the limit be within the detection range of portable XRF units?
- Will the limit be low enough to also address Occupational Health concerns?

Draft Scrap Clearance levels based on surface contamination by various metal thickness level

Summary

- XRF field technique offers a quick, real time and cost effective way of screening mercury surface contamination
- XRF technology adopted in other industries. Electronics industry use XRF to test electric/electronic products for compliance with EU Restriction of Hazardous Substance (RoHS) directive –July 2006
- Growing use of XRF technology for first step screening of exposure/contamination and in some cases for confirmatory testing
